Current Economic Conditions and Selected Forecasts

Summary

U.S. real GDP growth has been positive for 18 consecutive quarters, and the economy is considered to be in an “expansion” phase. As of the second quarter 2006, real or inflation-adjusted growth was nearly 16% above its previous high near the end of the 1991-2001 expansion.

Real GDP grew at an annualized quarterly rate of 2.5% in the second quarter of 2006, down from a 5.6% rate during the first quarter. This compares with annualized rates of 3.4%, 3.3%, 4.2%, and 1.8%, respectively, over the four quarters of 2005. The corresponding rates over the four quarters of 2004 were 3.9%, 4.0%, 3.1%, and 2.6%.

The rebound in payroll employment has been modest compared with past expansions. During July 2006, it was about 4.3 million above the level prevailing at the end of the recession (November 2001), but only about 2.8 million above the peak of the last expansion (March 2001). The unemployment rate rose to a high of 6.3% in June 2003; it has since declined and now (July 2006) stands at 4.8%, up from an expansion low of 4.6% (achieved in May). The low achieved during the last expansion was 3.8%.

The other elements in the economic picture are promising:

(1) A pick-up in output at the same time as employment is growing slowly means that productivity (or output per worker) is increasing. As seen in the 1990s, productivity growth is the key to raising the standard of living and is not necessarily associated with weak labor markets over time. The United States eventually experienced *both* rapid productivity and strong employment growth as the recovery broadened and deepened throughout the decade.

(2) The inflation rate, measured by the CPI, rose 3.4% during 2005. This was largely driven by rising energy prices as the inflation rate excluding food and energy rose only 2.2%. For the three months ending in July 2006, it rose at an annual rate of 4.5%. Excluding food and energy, the annualized rate was 3.2%. Thus, it can be argued, the underlying rate of inflation appears to be rising as well.

The consensus among economists is that GDP will grow between 3.3% and 3.5% in 2006. The unemployment rate is expected to show little tendency to change. The inflation rate is expected to be higher than the rate that prevailed in 2005. On 17 occasions beginning on June 30, 2004, and concluding on June 29, 2006, the Federal Reserve has increased the federal funds rate target by $\frac{1}{4}\%$, raising the target to $5\frac{1}{4}\%$ from 1%. No additional tightening was undertaken at its meeting on August 9. Fiscal policy tightened during 2005 and 2006. The international trade deficit is large and expected to remain so. This report will be updated monthly.

Current Economic Conditions and Selected Forecasts

Current Economic Conditions

Overview

U.S. economic growth has been positive during each of the past 18 quarters. The National Bureau of Economic Research (NBER) declared that the recession that began in March 2001 ended in November 2001. As of the first quarter 2006, U.S. real GDP (measured in 2000 dollars) was nearly 16% above its recession low point in the third quarter 2001, and had grown about 15% from its previous high near the end of the 1991-2001 expansion.

According to the most recent GDP report, growth in the second quarter of 2006 was at an annual rate of 2.5%, down from 5.6% in the first quarter (compared with 3.4%, 3.3%, 4.2%, and 1.8% during the four quarters of 2005). The comparable quarterly rates recorded during 2004 were 3.9%, 4.0%, 3.1%, and 2.6%.¹ Growth excluding inventories was at an annual rate of about 2.1%, down from 5.6% in the first quarter.² Contributions to GDP came mainly from consumption and investment in equipment and software.

Yet, despite the recovery in growth and other positive signs, concerns remain. The rebound has translated into only a modest rise in payroll employment above the level attained at the end of the previous cyclical peak. Since its peak in March 2001, payroll employment has risen by about 2.9 million. An encouraging sign is that employment has grown by more than 5.1 million since September 2002. The unemployment rate now stands at 4.8%, up from an expansion low of 4.6% first achieved in May. It has varied between 4.6% and 5.0% over the past 12 months. These rates are still above the 3.8% low of the 1990s expansion.

¹ The estimate of second quarter 2006 GDP growth is from the first (or “advance”) estimate.

² The accounting framework that governs the calculation of GDP is not always straightforward. In the GDP accounting rules, inventories subtract from growth if they are drawn down more in a particular quarter. However, in some circumstances, the drop in inventories might point to stronger growth ahead. For example, if domestic demand (defined as GDP other than inventories) accelerates at the same time inventories are drawn down, the standard interpretation is that growth will probably be higher in the near future. The reason why a pick-up is anticipated would be at least technical: with demand on the rise, inventories will not be sufficient after a while and new production will eventually be required to keep up with demand. New production increases GDP, according to the accounting framework. A pick-up may also signal underlying acceleration in the economy. quarter data. A similar signal was evident in the third quarter estimate.

Measured or headline inflation appears to be inching upwards. The broadest measure of inflation for the economy, the GDP price index, rose 3.1% over the four quarters of 2005, up from 2.6% in 2004 and 1.8% in 2003. The Consumer Price Index (CPI) followed a similar path. For the 12 months ended in May 2006, it rose 5.7% compared with 3.4% during 2005, 3.3% in 2004 and 1.9% in 2003. Both indexes have been heavily influenced by sharp movements in energy prices.

Monetary Policy

The policy of monetary easing that began in January 2001 ended in mid-2004. During this period, the Federal Open Market Committee (FOMC) of the Federal Reserve System lowered the federal funds target rate in 13 steps by a cumulative 550 basis points (5.50 percentage points), from 6.5% to 1.0% (its lowest level since April 1961). As the expansion gathered momentum and the possibility of inflationary pressures rising, the FOMC began to move the federal funds target upward. On each of 15 separate occasions, June 30, August 10, September 21, November 10 and December 14, 2004, February 2, March 22, May 3, June 30, August 9, September 20, November 1, and December 9, 2005, and January 31, March 28, May 10, and June 29, 2006, the target was advanced by 0.25%. It now stands at 5.25% (no additional tightening was made at the meeting of August 9).

Details

GDP. To understand the most recent macroeconomic developments, it may be important to understand aspects of the previous business cycle. The growth rate of GDP since 1991 is shown in **Table 1**. Its most notable feature is that after a weak start, the growth rate of GDP averaged more than 4% per year during the second half of the last expansion (1995-2000). GDP growth began to slacken during the second half of 2000 and actually contracted during 2000:3Q, 2001:1Q, and 2001:3Q. This pattern was reversed beginning with 2001:4Q when GDP grew positively, at an annual rate of 1.6%. During 2004, the annualized quarterly rates of growth were 4.3%, 3.5%, 4.0%, and 3.3%. During the four quarters of 2005, GDP grew at annual rates of 3.4%, 3.3%, 4.2%, and 1.8%, respectively. During the first two quarters of 2006, the annualized rates were 5.6% and 2.5%.

Productivity gains have been an important part of the current expansion.³ Most economists refer to recent trends as reflecting a “productivity-led” recovery. During 2002, 2003, 2004, and 2005, productivity rose 4.1%, 3.9%, 3.5%, and 2.6%, respectively. To put these numbers into perspective, the underlying productivity trend from 1973 to 1995 was for 1.4% annual growth; and the “step-up” in productivity from 1995 to 2000 was to a 2.5% annual rate of productivity growth. In the previous expansion, strong productivity gains were not part of the initial recovery phase after March 1991 and did not show up in the aggregate data until 1995.

³ Productivity is measured by output per hour of all persons. In the current situation, change in both the numerator and denominator of this ratio have been contributing to higher productivity: output (the numerator) has been rising and hours (denominator) have been declining.

Labor Markets. The civilian unemployment rate fell from a cyclical high of 7.8% in June 1992 to a low of 3.8% in April 2000, as shown in **Table 2**. At 3.8%, the unemployment rate was at a 30-year low. With a weakening of growth and a contraction followed initially by a modest recovery, the unemployment rate reversed course and rose, reaching a high of 6.3% in June 2003. Since then it has declined and is now at 4.8%, up from an expansion low of 4.6% achieved in May. During the past two years, the unemployment rate has varied between 4.6% and 5.7%.

Employment is now above its pre-recession peak. Measured from the end of the previous peak in March 2001, payroll employment has risen by approximately 2.9 million. This is unprecedented in any postwar business cycle. Even in the previous business cycle in the early 1990s (which was referred to initially as a “jobless” recovery”), employment had turned substantially upward by this point. Since the upswing began in November 2001, payroll employment has risen nearly 4.5 million.

Part of the reason for the low rate of job creation in the current expansion may be that employment at the end of the last expansion was substantially above the level many economists believed to be consistent with full employment. Thus, employment levels were expected to adjust downward and the data may be picking up this adjustment.

Divergence in payroll and household surveys? An interesting and perhaps important feature of the present economic expansion is the divergence between the two main measures of employment. The payroll survey shows that employment has increased by 2.9 million since the peak of the last expansion in March 2001 (and 4.5 million since the trough in November 2001). Less well known is the fact that the other main measure of employment (the household survey of the Bureau of Labor Statistics) indicates that employment has increased by about 6.5 million since the peak of the last expansion (and 8.1 million since the trough. Does the difference between the two measures of employment reflect statistical problems? Experts do not know. Some economists also note that self-employment trends are more accurately captured by the household survey (the payroll survey does not measure self-employment) and that household employment trends have often been reliable forward indicators of coming improvement in payroll employment in the aftermath of a recession.

Inflation. The U.S. inflation performance has been remarkable over the past 10 years. The inflation rate decelerated throughout most of the expansion in the 1990s, as **Tables 3 and 4** illustrate. Toward the end of the expansion in 2000, the inflation rate accelerated, but the pick up was not noticeably different from earlier years of the cycle.

During the 1991-2001 expansion, the inflation rate increased more slowly on average than at any time since the early 1960s. At the same time, growth was stronger and the unemployment rate lower than experience would have predicted. Inflationary pressures slowed further with the recession. Moreover, the deceleration in inflation over the 1990s occurred even as the pace of growth accelerated. In the postwar experience, this combination of developments is unusual. The rates of growth and inflation have not typically moved in the opposite direction, particularly when the unemployment rate was sustained at a relatively low level close to 4.0% in what was generally considered to be an economy at or above full employment.

Source: U.S. Department of Commerce.

With the start of the recession in March 2001, inflation rate decelerated, excluding energy prices. The increase in consumer prices (the Consumer Price Index or CPI) slowed on a year-year basis from 2.8% in 2001 to 1.6% in 2002. The rate of increase in the GDP deflator, the broadest measures of inflation in the economy, decelerated from 2.2% in 2000 to 1.7% in 2002, on a fourth quarter-fourth quarter basis. Since then it has been rising, reaching 2.9% during 2004 and 3.1% during 2005. During 2006:1H, it rose at an annual rate of 3.3%.

Table 4. Rate of Change in the Consumer Price Index (CPI), 1993-2005
(percent)

	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005

Excluding food and energy	3.3	2.8	3.0	2.7	2.4	2.3	2.1	2.4	2.6	2.4	1.4	1.7	2.2

Source: U.S. Department of Labor.

This pattern can be found in the CPI. Measured on a December-December basis, it rose by 2.4% during 2002, decelerated to 1.9% during 2003, and then accelerated to 3.3% during 2004 and 3.4% during 2005. Much of the acceleration can be attributed to energy price increases. For the 12 months ended in June, it rose 4.1%. Excluding food and energy, the increase was 2.7%.

The rate at which Unit Labor Costs have risen has been low over four of the last five years, as shown in **Table 5**. Employee cost trends are also measured in the Employment Cost Index (ECI). The rate at which the ECI for private industry rose accelerated from 1995 through most of 2001, but began to decelerate in the course of 2002 as a result of weakened labor market pressures. The ECI began a very modest rise beginning in 2003, somewhat in line with increases during the late 1990s.

Table 5. Rate of Change in Labor Costs, 1993-2005
(in percentages)

	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005
Unit Labor Costs	1.6	0.5	2.1	0.7	2.0	2.7	1.6	4.3	0.4	0.2	0.5	1.8	1.6

Source: U.S. Department of Labor.

Notes: Unit labor costs are for nonfarm business, 4th quarter-4th quarter. The Employment Cost Index is for private industry on a December-December basis.

Between December 2005 and June 2006, the ECI rose at an annual rate of 2.8%, and between 2005:4Q and 2006:4Q, Unit Labor Costs rose at an annual rate of 3.3%.

The U.S. Foreign Trade Deficit. The U.S. foreign trade deficit (net imports), as shown in **Table 6**, recorded a continued and dramatic fall from 1988 through 1992.⁴ In these years, the trade deficit declined as export growth exceeded import growth. During 1993 the trade deficit began to grow as a fraction of GDP, and during the first half of 2006, it averaged 5.6% of GDP. The increase in the U.S. foreign trade deficit during 1992-2005 is a reminder that the United States still receives a substantial net inflow of capital from abroad.

Table 6. U.S. Foreign Trade Deficit, 1989-2005
(as a percent of GDP)

1989	1990	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005

The U.S. Dollar. **Figure 1** records the movement in the foreign exchange value of the dollar measured against a trade-weighted index of the currencies of many U.S. trade partners over the past 15 years. After hitting a low in the second quarter 1995, the dollar rose in real or inflation-adjusted terms (that is, it appreciated) by over 34% to its peak in February 2002. From then until December 2004, it depreciated by about 16% on an inflation-adjusted basis, with some ups and downs. From December 2004 through June, 2006, the dollar appreciated 2.7%.

⁴ The foreign trade deficit figure analyzed above is different from the headline trade deficit reported in the press and another trade deficit ratio often used by economists, although they are all related and can be reconciled. In this report, the “trade deficit” refers to exports and imports from the U.S. national accounts, which are the basis for the GDP figures. The underlying data for the figures cited above are released quarterly and annually and are on an inflation-adjusted basis (“real”). In contrast, foreign trade figures frequently quoted in the press are different because they released monthly rather than quarterly, not adjusted for inflation and are defined slightly differently otherwise. These figures are usually not compared to GDP. To make matters even more confusing, economists often refer by convention to the quarterly trade figures known as the current account. The current account position includes components not in the figures above and is not adjusted for inflation. For 2002, 2003, 2004, and 2005, the current account deficit was, respectively, approximately 4.1%, 4.6%, 5.2%, and 5.8% of nominal GDP. During 2006:1H, it rose to 5.9% of Nominal GDP.

Figure 1. Real Dollar Exchange Rate (Broad Dollar Index)

Source: Board of Governors of the Federal Reserve System.

The dollar has shown more movement against the major world currencies than the broad trade-weighted index described above suggests.⁵ From its high in February 2002 through December 2004, the dollar has depreciated some 7% against an index consisting of the major currencies that circulate, adjusted for inflation. However, over the period December 2004 to June 2006, this index shows that the dollar has risen in value by about 5.4%.

Posture of Fiscal and Monetary Policy

The course of GDP growth can respond significantly to changes in fiscal and monetary policy.

Fiscal Policy

The posture of fiscal policy depends on how it is measured. A generally accepted method is to examine the ratio of the structural or full employment budget deficit to full employment GDP. When that is done, as shown in **Table 7**, fiscal policy was expansionary between 2001 and 2003 as a full employment surplus in 2001 fell from 1.1% to a deficit of 2.7% of potential GDP in 2003. The deficit declined to 2.4% of potential GDP in 2004, and 1.8% in 2005. An alternative, although inferior measure, is the ratio of the actual budget deficit to actual GDP. When examined, fiscal policy was also expansionary between 2000, with the surplus of 2.4%, to a deficit of 3.5% in 2004, a net shift of 6% of GDP. In 2005, the deficit fell to 2.6% of GDP, a shift toward fiscal tightness.

⁵ In **Figure 1**, the dollar is measured against an index of the currencies of many of the major trade partners of the United States weighted according to the proportion of trade. This is referred to as the “broad dollar index.” The Board of Governors also publishes the exchange rate of the dollar with the currencies of smaller groups of countries or individual countries.

Monetary Policy

Traditionally, the posture of monetary policy has been judged either by the growth of the monetary aggregates or by movements in interest rates.⁶ The three monetary aggregates, as shown in **Table 8**, have not responded uniformly to the easing of monetary policy. The rate of growth of M1 in 2003 exceeded 2002. The reverse was true for M2 and M3.

The positive growth in aggregate reserves over 2002-2004 support the Federal Reserves view that it is providing important support to the ongoing expansion. The continued rapid growth of the monetary base reflects in part the growth in reserves. However, it mainly reflects the growth in paper currency in circulation since about 90% of the base is accounted for by currency (the great portion of which does not circulate in the United States). Nevertheless, the various measures of money do not provide consistent measures of the thrust of monetary policy.

⁶ For a more comprehensive discussion of monetary policy, see CRS Report RL30354, *Monetary Policy: Current Policy and Conditions*, by Marc Labonte and Gail Makinen.

a. Data on M3 ceased to be published after March 2006.

The growth in the reserves of depository institutions results to a large degree from decisions to move the key federal funds' interest rate (shown in **Figure 2**), the principal tool of monetary policy. These moves have been motivated primarily by a desire to bring the economy to full employment and then keep it growing at a rate sufficient to maintain full employment. From time to time, other factors may influence the movement of this rate. For example, the turmoil in both domestic and international financial markets during 1998 caused the rate to be reduced ¼% on September 29, October 15, and November 17 of that year. And in response to the September 11, 2001, terrorist attacks, the rate was reduced ½% on September 17.

During the past two years, the target rate has been gradually increased. In a series of 17 steps, each ¼% in magnitude, the target was raised to 5¼% on June 29, 2006, from 1% on June 25, 2005. The target was unchanged at the August 9 meeting.

As **Figure 2** shows, movements in short-term interest rates mimic closely movements in the federal funds rate. This is not as true for longer-term rates. Their rise and fall as well as the magnitude of their shifts is often different from the timing and magnitude of shifts in the federal funds rate. This is due in part to the fact that they respond to the longer run outlook for inflation, the financing requirements necessitated by the budget deficit, both current and prospective, and the international flow of capital.

Economic Forecasts, 2006-2007

The forecasts in **Table 9** come from three sources. OMB and CBO are well known. BC stands for the Blue Chip Economic Indicators, a firm that collects the forecasts from about 50 forecasters in finance, business, and universities. BC Con represents the consensus or average forecasts of this group. BC T-10 is the average of the high ten among these forecasts, while BC B-10 is the average of the low 10 forecasts.

The consensus view taken by the forecasts summarized in **Table 9** is that GDP growth should be about 3.4% during 2006, which is near to what is generally considered the rate of U.S. potential growth. This rate of GDP growth, according to the consensus, however, will be insufficient to have other than a modest effect on the unemployment rate. The consensus anticipates that the unemployment rate will remain largely unchanged. The inflation rate for the entire economy is expected to range between 2.4% and 3.2%, depending on the price index consulted. Both short-term and long-term interest rates are expected to trend upward in 2006 from levels attained in 2005.

In its semiannual *Monetary Policy Report to the Congress*, dated July 19, 2006, The Board of Governors of the Federal Reserve presented its economic projections for 2006 and 2007. It projected that from the fourth quarter 2005 to the fourth quarter 2006, real GDP will grow about 3.5% and that prices⁷ will increase about

⁷ In its *Monetary Report to Congress*, the Federal Reserve features in its projections a measure of inflation derived from the Personal Consumption Expenditure (PCE), less food and energy, index found in the GDP accounts. This price index attempts to measure inflation (continued...)

2.25% to 2.5%. The civilian unemployment rate is projected to be average between 4.75% and 5.0% during the fourth quarter of the year. For 2007, real GDP, on a fourth quarter over fourth quarter basis, is projected to grow between 3.0% and 3.25%, prices are expected to rise between 2.0% and 2.25%, and unemployment during the fourth quarter of the year is projected to average between 4.75% and 5.0%.

Special Topics

Accounting for GDP Growth

Table 10 records contributions to growth in GDP from 1995 to 2004. These data record two interesting developments. First, investment spending played an important role in the 1991-2001 expansion. Its contribution to GDP growth was unusually large during most of that period. And among the categories of investment, outlays for personal computers were important. This bodes well for the longer run growth in productivity. Second, purchases by all levels of government played only a small role in that expansion. The relative contribution of consumption did not

change significantly during this period, although it continued to be the largest single contributor to GDP growth.

Promotion of Economic Growth: The Importance of Saving

Over the longer run, the economic well-being of a nation depends on the growth of potential output or GDP per capita. Crucial to this growth is the fraction of a nation's resources devoted to capital formation. The ability to add to the capital stock through investment depends on a nation's saving rate.

Saving comes from several sources. In the private sector individuals (households) and businesses are responsible for saving. The former save when all of their after tax income is not used for consumption. Businesses save through retained earnings and capital consumption allowances.

The public sector can also be a source of national saving and this occurs when government revenues are larger than expenditures. Budget surpluses, then, can be viewed as a source of national saving.

Table 11 shows the sources of saving for the United States during the past 45 years. There are several things to note about these data. First, except for the decade of the 1990s, the gross private sector savings rate has averaged a remarkably stable 17%-19% of GDP, with most of the saving being done by businesses. More significantly, however, the private sector saving rate net of depreciation, representing saving available for additions to capital, declined considerably in the 1990s. The drop in the household (personal) savings rate has been the major factor in the decline in the private sector saving rate. Thus, even without a federal budget deficit, the United States would have had a "saving problem."

Second, over this 45-year period, the saving done by the public sector, as a whole, has declined. There is, however, diversity as to the contribution made by the level of government. The large negative contribution made by the federal

government during the 1980s and 2002-2004 reflects the widely publicized budget deficit. Even though state and local governments have been running budget surpluses, they have not been large enough to offset the federal deficits. This was reversed during the period 1993-2001. The improved budget position of the federal government during this period added to national saving.

Third, the data show that for 20 of these 45 years, the United States exported a small fraction of its savings to the rest of the world (i.e., was a net exporter of capital). This changed during the 1980s when the United States began to import the savings of the rest of the world.

The United States has been able to sustain its growth and standard of living since the 1980s because we have been able so far to attract sufficient capital (saving) from international investors. Without these saving, the United States had a “financing gap” in view of its domestic saving shortfall relative to its demand for investment capital. In the absence of sufficient capital, U.S. interest rates would have had to rise in order to restore balance between investment and a now smaller amount of saving. Higher interest rates would have choked off investment and dampened U.S. growth.⁸

Should efforts to correct the international trade deficit prove fruitful, the net inflow of foreign saving will diminish or perhaps on net cease (that is, stabilize). Should this occur without a significant improvement in either the private sector saving rate or the negative saving rate of the public sector, the rate of new investment will fall to a very low level in the United States and with it the means for improving the well-being of future generations of Americans.

A sudden increase in the national saving rate is, however, not without some possible adverse consequences. In the short run, a sudden increase in the saving rate means decreased consumption or lower public sector net spending, both of which depress aggregate demand. Moreover, in either case, the demand for some types of output would fall to be replaced by an increased demand for other types of output. As a result, some industries and firms would have to contract while others expand. Resources would have to transit from declining to growing industries. These short-run dislocations should be borne in mind if a higher national saving rate becomes the object of public policy.
